6.6 Intruders and Moving Constraints

Intruder behaviour: Adversarial behaviour of moving obstacle is trying to destroy avoiding our UAS. The Intruder UAS [1] is not trying to hurt our UAS actively. The Adversarial behaviour is neglected in this work. The non-cooperative avoidance is assumed, it can be relaxed to cooperative avoidance in UTM controlled airspace.

Intruder information: The observable intruder information set for any kind of intruder, obtained trough sensor/C2 line, is following:

- 1. Position position of intruder in local or global coordinate frame, which can be transformed into avoidance grid coordinate frame.
- 2. Heading and Velocity intruder heading and linear velocity in avoidance grid coordinate frame.
- 3. Horizontal/Vertical Maneuver Uncertainty Spreads how much can an intruder deviate from original linear path in horizontal/vertical plane in Global coordinate Frame.

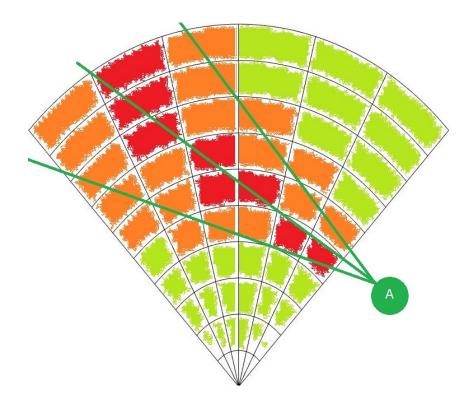

Figure 6.1: Intruder UAS intersection rate along expected trajectory.

Example of Intruder Intersection: Lets neglect the time-impact aspect on intersection. The intruder (black "I" circle) is intersecting one avoidance grid horizontal slice (fig. 6.1). The intruder is moving along linear path approximation based on velocity (middle green line). The Horizontal Maneuver Uncertainty spread is in green line boundary area intruder intersection rating is denoted as green-orange-red cell fill reflecting intersection

severity: red is high rate of intersection, orange is medium rate of intersection and green is low rate of intersection.

Moving Threats: The *UAS* can encounter following threats during the *mission execution*:

- 1. Non-cooperative Intruders the intruders whom does not implement any approach to ensure mutual avoidance efficiency.
- 2. Cooperative Intruders the intruders whom actively communicate or follow common agreed behaviour pattern (ex. Rules of the Air).
- 3. Moving Constraints the constrained portion of free space which is shifting its boundary over time (ex. Short term bad weather).

Note. Our approach considers only UAS intruders, because $Data\ Fusion$ considers data received trough ADS-B messages. The Intruders extracted from LiDAR scan were not considered (ex. birds). The proposed $intruder\ intersection\ models$ are reusable for other $intruder\ sources$.

Approach Overview: The Avoidance Grid (def. ??) is adapted to LiDAR sensor. The euclidean grid intersections are fairly simple. The polar coordinates grid are not. The need to keep polar coordinates grid is prevalent, because of fast LiDAR reading assessment. There are following commonly known methods to address this issue:

- 1. Point-cloud Intersections the threat impact area is discredited into sufficiently thick point cloud. This point-cloud have point impact rate and intersection time assigned to each point. The point-cloud is projected to Avoidance Grid. If impact point hits $cell_{i,j,k}$ the cell's impact rate is increased by amount of point impact rate. The final threat impact rate in $cell_{i,j,k}$ is given when all points from point cloud are consumed. Close point problem [2] was solved by application of method [3].
- 2. Polygon Intersections the threat impact area is modeled as polygon, each $cell_{i,j,k}$ in Avoidance Grid is considered as polygon. There is a possibility to calculate cell space geometrical inclusive intersection. The impact rate is then given as rate between intersection volume and $cell_{i,j,k}$ volume. The algorithm used for intersection selected based on:[4] the selected algorithm Shamos-Hoey [5].

Note. The Intruder Intersection models are based on analytically geometry for cones and ellipsoids taken from [6].

6.6.1 Intruder Behaviour Prediction

Idea: Intruder Intersection Models is about space-time intersection of intruder body with avoidance Grid and Reach Set:

- 1. The UAS reach set defines time boundaries to enter/leave cell in avoidance grid.
- 2. The *Intruder* behavioral pattern defines *rate* of *space intersection* with cell bounded space in avoidance grid.

The multiplication of space intersection rate and time intersection rate will give us intruder intersection rate for our UAS and intruder.

Intruder Dynamic Model: The definition of avoidance grid enforces the most of these methods to be numeric. Let us introduce intruder dynamic model:

$$position_x(t) = position_x(0) + velocity_x \times t$$

$$dposition/dtime = velocity \mid position_y(t) = position_y(0) + velocity_y \times t \qquad (6.1)$$

$$position_z(t) = position_z(0) + velocity_z \times t$$

Position vector in euclidean coordinates [x, y, z] is transformed into Avoidance Grid coordinate frame. Velocity vector for [x, y, z] is estimated and not changing. The time is in interval [entry, leave], where entry is intruder entry time into avoidance grid and leave is intruder leave time from avoidance grid.

Note. If intruder is considered, time of entry is marked as $intruder_{entry,k}$ where k is intruder identification, time of leave is marked as $intruder_{leave,k}$ where k is intruder identification.

Cell Entry and Leave Times $UAS_{entry}(cell_{i,j,k})$ and $UAS_{leave}(cell_{i,j,k})$ are depending on intersecting Trajectories and $bounded\ cell\ space\ (eq.\ \ref{eq.}?)$. There is $Trajectory\ Intersection$ function from (def. $\ref{eq.}$?) which evaluates $Trajectory\ segment$ entry and leave time.

The UAS *Cell Entry* time is given as minimum of all *passing trajectory segments* entry times (eq. 6.2), if there is no *passing trajectories* the UAS *entry time* is set to 0.

$$UAS_{entry}(cell_{i,j,k}) = \min \begin{cases} 0, entry(Trajectory, cell_{i,j,k}) :\\ Trajectory \in PassingTrajectories \end{cases}$$
(6.2)

The UAS *Cell Leave* time is given as maximum of all *passing trajectory segments* entry times (eq. 6.3), if there is no *passing trajectories* the UAS *leave time* is set to 0.

$$UAS_{leave}(cell_{i,j,k}) = \max \begin{cases} 0, leave(Trajectory, cell_{i,j,k}) : \\ Trajectory \in PassingTrajectories \end{cases}$$
(6.3)

Time Intersection Rate: The key idea is to calculate how long the UAS and Intruder spends together in same space portion $(cell_{i,j,k})$. The Intruder can spent some time in $cell_{i,j,k}$ bounded by interval of intruder entry/leave time.

The *UAS* can spent some time, depending on *selected trajectory* from *Reach Set*. The time spent by UAS is bounded by entry (eq. 6.2) and leave (eq. 6.3).

The intersection duration of these two intervals creates time intersection rate numerator, the maximal duration of UAS stay gives us denominator. The time intersection rate is formally defined in (eq. 6.4).

$$time \begin{pmatrix} UAS, \\ Intruder, \\ cell_{i,j,k} = \circ \end{pmatrix} = \frac{\begin{vmatrix} [intruder_{entry}(\circ), intruder_{leave}(\circ)] \\ \cap \\ [UAS_{entry}(\circ), UAS_{leave}(\circ)] \\ |[UAS_{entry}(\circ), UAS_{leave}(cell_{\circ})]| \end{vmatrix}}{(6.4)}$$

Intruder Intersection Rate: The *Intruder Intersection Rate* (eq. 6.5) is calculated as *multiplication* of *space intersection rate* (defined later) and *time intersection rate* (eq. 6.4).

$$intruder \begin{pmatrix} UAS, \\ Intruder, \\ cell_{i,j,k} \end{pmatrix} = time \begin{pmatrix} UAS, \\ Intruder, \\ cell_{i,j,k} \end{pmatrix} \times space \begin{pmatrix} UAS, \\ Intruder, \\ cell_{i,j,k} \end{pmatrix}$$
 (6.5)

Note. If there is no information to derive Intruder entry/leave time for cells the time intersection rate is considered 1.

The *Intruder cell reach* time (eq. 6.6) is bounded to discrete point in intersection model [2, 3]. The intruder *entry/leave time* is calculated similar to *UAS cell entry (eq. 6.2)/leave (eq. 6.3) time*.

$$pointReachTime(Intruder, point) = \frac{distance(Intruder.initialPosition, point)}{|Intruder.velocity}$$
(6.6)

Space Intersection Rate: The *Space Intersection Rate* reflects probability of *Intruder* intersection with portion of space bounded by $cell_{i,j,k}$, to be precise with intruder trajectory or vehicle body shifted along the trajectory. The principles for *space intersection* rate calculation are following:

- 1. Line trajectory intruder trajectory is given by linear approximation (eq. 6.1), depending on intruder size the intersection with avoidance grid can be:
 - a. Simple line intersection is going along the trajectory line line defined by intruder model (eq.6.1).

- b. Volume line intersection is going along the trajectory line defined by intruder model (eq. 6.1) and intruder's body radius is considered in intersection.
- 2. Elliptic cone initial position is considered as the top of a cone, the main cone axis is defined by intruder linear trajectory (eq. 6.1) $time \in [0, \infty]$. The cone width is set by horizontal and vertical spread.

6.6.2 Linear Intersection

Idea: There are *small intruders* which have body *smaller* than average $cell_{i,j,k}$ cell size. Its trajectory will stick to *linear trajectory* prediction with high probability.

Space Intersection Rate: The *Space Intersection Rate* for $cell_{i,j,k}$ is implemented as simple point cloud intersection. Where *sufficiently thick* point cloud is defined along *line* (eq. 6.7):

$$position(time) = position(time_0) + velocity \times time, \quad time \in [0, \infty[$$
 (6.7)

Then there exist projection function from local euclidean coordinates to local polar coordinates (eq. 6.8. The function projects intruder trajectory (eq. 6.7) to planar coordinates [distance, horizontal°, vertical°] as a set of sufficiently thick point cloud.

$$polarSet: position(t) \rightarrow \{[distance, horizontal^{\circ}], vertical^{\circ}\}\$$
 (6.8)

The space intersection rating $SpaceIntersection(\circ)$ for line type is given as (eq. 6.9). If there exist non empty intersection of $polarSet \cap cell_{i,j,k}$ there is space intersection rate equal to 1, if intersection $polarSet \cap cell_{i,j,k} = \emptyset$ then the rate is zero.

$$space \begin{pmatrix} Intruder, \\ cell_{i,j,k} \end{pmatrix} = \begin{cases} 1: & \exists point \in polarSet(eq.6.8) : point \in c_{i,j,k} \\ 0: & \text{otherwise} \end{cases}$$
(6.9)

Note. The intruder intersection rate is multiplication of space intersection rate and time intersection rate. The intersection rate is calculated for every intruder and selected intersection model separately.

6.6.3 Body-volume Intersection

Idea: The *Intruder* has body volume greater than average $cell_{i,j,k}$ volume. The *intruder* body is considered as the ball moving along intruder position. The intersection of the intruder body is realized as sufficiently thick point-cloud intersection.

Space Intersection Rate - Body Volume: The body volume mass with center at position(t) is moving along intruder trajectory prediction (eq. 6.10) in time interval $[0, \infty[$:

$$position(time) = position(time_0) + velocity \times time$$
 (6.10)

The body $Volume\ ball\ Body(position(t), radius)$ (eq. 6.11) is defined as set of points in \mathbb{R}^3 euclidean space. The center is moving along the position(t). The body $volume\ ball$ is a set of points sufficiently thick including also inner points. The thickness is guaranteed by existence of neighbour point which is close enough.

$$Body(position(t), radius) = \begin{cases} ||position(t) - point|| \le radius \\ point \in \mathbb{R}^3 : \forall point_i \exists point_{j \ne i}, \\ distance(point_i, point_j) \le thickness \end{cases}$$

$$(6.11)$$

The polar volume ball polar Body (eq. 6.12) is projection of body volume ball set Body(position(t), radius) to a set of planar coordinates in avoidance grid coordinate frame:

$$polarBall(t): Body(position(t), radius) \rightarrow \left\{ \begin{bmatrix} distance, horizontal^{\circ}, \\ vertical^{\circ}, intersectionTime \end{bmatrix} \right\} \quad (6.12)$$

The space intersection rate for vehicle body space(Intruder, $cell_{i,j,k}$) (eq. 6.13) is calculated as intersection of polar body volume ball and $cell_{i,j,k}$. If intersection is non empty then base probability is one, zero otherwise:

$$space \begin{pmatrix} Intruder, \\ cell_{i,j,k} \end{pmatrix} = \begin{cases} 1: & \exists point \in polarBall(eq.6.12) : point \in c_{i,j,k} \\ 0: & \text{otherwise} \end{cases}$$
 (6.13)

Intersection Time: The *intersection time* id depending on point cloud (eq. 6.12) where each point have intersection time given as body-center position time (eq. 6.10).

Note. The body-volume intersection model, can insert the multiple intersection times into one $cell_{i,j,k}$. the interval length considers all of these for intersection rates (eq. 6.4).

6.6.4 Maneuverability Uncertainty Intersection

Idea: The *intruders* are not bullets they are not sticking to predicted linear paths. The *intruder* maneuverability is given as horizontal and vertical spread. Therefore *intruder reach set* will form a *elliptic cone*. This cone can be transformed into *finite discrete* point-cloud, each *point* should have assigned *severity* impact value. The point cloud intersection with *Avoidance Grid* will give us space impact of *uncertain* intruder.

Note. Following section will use condensed notation, due the equation complexity. The *terminology* is consistent with rest of section.

Sprace Intersection Rate - Body Volume Intersection: $P_T(i_k(x_s, v, \theta, \varphi), c_{i,j,k})$ computation is less straight-forward than other space intersection rates. First let us define the linear intruder i_k positions x at time t (eq. 6.14) model, where x(t) defines intruder position in avoidance grid euclidean coordinate frame at time t_i , v defines intruder velocity, and t is time offset.

$$x(t) = x_s + v_I.t (6.14)$$

Intruder horizontal spread θ and vertical spread φ are introduced. These spreads represents intruder deviation limits along from linear trajectory prediction $x(t) \in \mathbb{R}^3$. The example is given by (fig. 6.2) where the intruder starts at point x_s with fixed velocity v, the linear trajectory prediction is outlined by blue line. The predicted intruder position at time t = 10s is given by x(10) (blue point). The ellipsoidal space E(x) is projected on the plane D(x(t)). The plane D (eq. 6.15) for point x(t) and velocity v is defined as an orthogonal plane to velocity vector $v \in \mathbb{R}^3$ with origin at intruder position x(t).

$$D(x(t), v) = \{ a \in \mathbb{R}^3 : (a - x(t)) \perp v, \}$$
(6.15)

To construct ellipsoidal space boundary on orthogonal plane D(x(t), v) some parameters are defined in (eq. 6.16). The scalar distance $d_dx(t)$ is simple euclidean norm, maximal horizontal offset $d_{\theta}(x_t)$ is given as product of sinus of horizontal offset angle θ and scalar distance d_d , and maximal vertical offset $d_{\varphi}(x(t))$ is given a product of sinus of vertical offset angle φ and scalar distance d_d .

$$d_d = d_d(x(t), x_s) = ||x(t) - x_s||_2$$

$$d_{\theta_{\text{max}}} = d_{\theta}(x(t)) = \sin \theta(i_k) . d_d(x(t))$$

$$d_{\varphi_{\text{max}}} = d_{\varphi}(x(t)) = \sin \varphi(i_k) . d_d(x(t))$$

$$(6.16)$$

The *Ellipsoid* E(x(t), v) (eq. 6.17) for fixed intruder position x(t) and fixed intruder velocity v is given as constrained portion of orthogonal plane D(x(t), v). The constraint is defined by an internal coordinate frame $p \in \mathbb{R}^2$ which is space reduction of plane D(x(t), v).

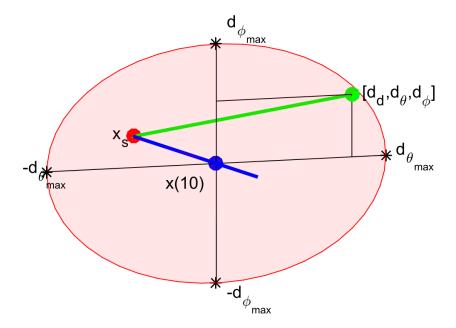

Figure 6.2: One rate position $[d_d, d_\theta, d_\varphi]$ (green). deviated from linear trajectory (blue line) at point x(10).(blue) with initial position x_s (red)

The internal coordinate frame $p \in \mathbb{R}^2$ has origin in $x(t) \to \mathbb{R}^2$. The points of plane p are bounded by projection $p = (b - x(t)) \to \mathbb{R}^2$, where $b \in D(x(t), v)$. The point of ellipsoidal p is then given as standard ellipse boundary with vertical span $d_{\theta}(x(t))$ and horizontal span $d_{\varphi}(x(t))$.

The 2D *Ellipsoid* E(x(t), v) for specific time t = 10s example is portrayed as red ellipsoid (in fig. 6.2).

$$E(x(t), v) = \begin{cases} b \in \mathbb{R}^3 : b \in D(x(t), v), p = (b - x(t)) \to \mathbb{R}^2, \\ \left(\frac{p(1)^2}{d_{\theta}(x(t))^2} + \frac{p(2)^2}{d_{\omega}(x(t))^2}\right) \le 1 \end{cases}$$
(6.17)

The expected behaviour of an intruder i_k is to stick to predicted linear trajectory x(t) (6.14). The probability of deviation should be decreasing with distance from ellipse center (fig. 6.3.).

Probability density function for ellipsoid E(x(t), v) defined in (eq. 6.17) is depending on maximal horizontal spread $d_{\theta}(x(t))$, maximal vertical spread $d_{\varphi}(x(t))$, defined by (eq. 6.16).

Two standard probabilistic distributions are established $\mathcal{N}(\mu_{\theta}, \sigma_{\theta})$ (eq. 6.18) for horizontal spread $\theta(x(t))$ and $\mathcal{N}(\mu_{\varphi}, \sigma_{\varphi})$ (eq. 6.19) for vertical spread $\varphi(x(t))$. The means μ_{θ} and μ_{φ} are set to zero, and internal coordinate frame $p \in \mathbb{R}^2$ where $x(t) \to \mathbb{R}^2$ is frame center. The variances σ_{θ} and σ_{φ} are set as maximal distances on horizontal/vertical spread axes $d_{\theta}(x(t))$ and $d_{\varphi}(x(t))$.

$$P(x(t), d_{\theta}) = \mathcal{N}(\mu_{\theta}, \sigma_{\theta}) = \mathcal{N}(0, d_{\theta}(x(t)))$$
(6.18)

$$P(x(t), d_{\varphi}) = \mathcal{N}(\mu_{\varphi}, \sigma_{\varphi}) = \mathcal{N}(0, d_{\varphi}(x(t)))$$
(6.19)

The combined probability density function for maximal spreads d_{θ} and d_{φ} is given by (eq. 6.20). Because probability density function is defined for internal space $p \in \mathbb{R}^2$ and one may need to calculate impact rate for cell space $c_{i,j,k} \in \mathbb{R}^3$.

The reduction from two parameter probability distribution function to scalar rate distribution function is needed. An scalar rate distribution function $P(x(t), d_{\theta}, d_{\varphi})$ over ellipsoid E(x(t), v) is defined as (eq.6.20), where final rate is given as average of two partial probabilities.

Final space intersection rate $P(x(t), d_{\theta}, d_{\varphi})$ needs to be normalized to hold normal distribution condition (eq. 6.21). Normal distribution condition value (eq. 6.21) is given as surface integral over ellipsoid E(x(0), v) with rate distribution function $P(x(t), d_{\theta}, d_{\varphi})$.

$$P(x(t), d_{\theta}, d_{\varphi}) = \frac{\mathcal{N}(\mu_{\theta}, \sigma_{\theta}) + \mathcal{N}(\mu_{\varphi}, \sigma_{\varphi})}{2}$$
(6.20)

$$\iint_{E(x(\tau))} P(x(t), d_{\theta}, d_{\varphi}) \, \mathrm{d}d_{\theta} \, \mathrm{d}d_{\varphi} = 1 \tag{6.21}$$

Final space intersection rate $P(x(t), c_{i,j,k}, \theta, \varphi)$ (space portion, time portion is calculated in (eq.6.5) is given by (eq. 6.23). Its mean value of all intersection rates $P(x(\tau), c_{i,j,k}, \theta, \varphi)$ where $\tau \in [i_e(c_{i,j,k}), i_l(c_{i,j,k})]$ is fixed point in intersection time interval.

An $P(x(\tau), c_{i,j,k}, \theta, \varphi)$ (6.22) is integration of rate density function $P(x(\tau), d_{\theta}, d_{\varphi})$ (eq. 6.20) in surface $E(x(\tau), v)$ to cell $c_{i,j,k}$ volume intersection.

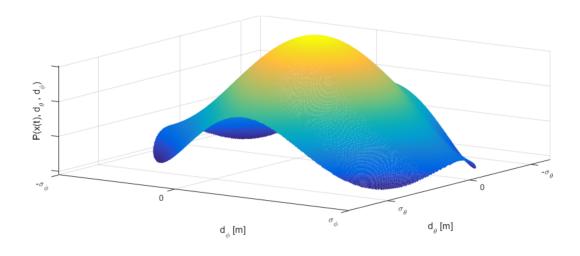

Figure 6.3: Probability of intruder i_k position in ellipsoid E(x(t), v)

To get a volume integration partial rate in surface intersection must be integrated and normalized in time interval $\tau \in [i_e(c_{i,j,k}), i_l(c_{i,j,k})]$, the base intersection probability $P_T(i_k(x_s, v, \theta, \varphi), c_{i,j,k})$ is given by (eq. 6.23). Example of intersection of intruder i_r uncertain ellipsoid cone with avoidance grid $\mathcal{A}(t_i)$ is given in (fig. 6.4).

$$P(x(\tau), c_{i,j,k}, \theta, \varphi) = \iint_{E(x(\tau), v) \cap c_{i,j,k}} P(x(\tau), d_{\theta}, d_{\varphi})$$
(6.22)

$$P_T(i_k(x_s, v, \theta, \varphi), c_{i,j,k}) = \frac{\int_{i_e(c_{i,j,k})}^{i_l(c_{i,j,k})} P(x(\tau), c_{i,j,k}, \theta, \varphi) d\tau}{i_l(c_{i,j,k}) - i_e(c_{i,j,k})}$$
(6.23)

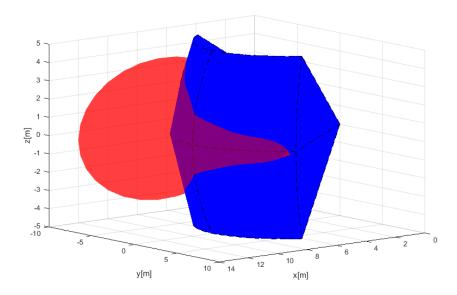

Figure 6.4: Avoidance grid $\mathcal{A}(t_i)$ (blue) intersection with elliptic cone intruder $i_k(x, v, \theta, \varphi)$ (red) example.

An numeric approximation of space intersection rate $P_T(i_k(x_s, v, \theta, \varphi), c_{i,j,k})$ is more implementation feasible than symbolic calculation due the multiple intersection constraints and bad intersection algorithm complexity.

Let us define homogeneous discrete subset of real numbers \mathbb{R} which is non empty subset of real numbers \mathbb{R} . The set \mathbb{R} (eq. 6.24) is homogeneous, that means for any equal interval $(i, i+1], i \in \mathbb{Z}$ subset the count of members is equal to some positive natural number k. The parameter k can be understand as unit approximation density.

Similarly the power sets $\mathcal{R}^2 \subset \mathbb{R}^2$, $\mathcal{R}^3 \subset \mathbb{R}^3$, ... $\mathcal{R}^i \subset \mathbb{R}^i$, $i \in \mathbb{N}^+$ keeps homogeneous distribution.

$$\mathcal{R} = \left\{ a \in \mathbb{R} : \forall i \in \mathbb{Z}, |i < a \le i + 1| = k, k \in \mathbb{N}^+, \\ \forall j \in \mathbb{N}^+ a_{j+1} - a_j = m, m \in \mathbb{R}^+ \right\}, \, \mathcal{R} \subset \mathbb{R}$$
 (6.24)

The orthogonal plane for $x(t), v, t \in \mathbb{R}$ is defined by (eq. 6.15). The orthogonality property is also kept for any subspace $\mathbb{R}^n \in \mathbb{R}^n, n \in \mathbb{N}^+$. Numeric approximation of D(x(t), v) is given as $D_D(x(t), v)$ (eq. 6.25).

The only difference is that discrete approximation is countable $|D_D| = m, m \in \mathbb{N}^+$, but continuous representation $|D| \approx \infty$ is uncountable. Because ellipsoid is subset of orthogonal plane it keep its countability property, therefore E_D is also countable and

must contains at-least one member.

$$D_D(x(t), v) = \{ a \in \mathbb{R}^3 : (a - x(t)) \perp v, \}, t \in \mathbb{R}$$
(6.25)

The base ellipsoid E(x(t), v) for continuous-space is given by (eq. 6.17). Every element, expect the base of internal projection \mathbb{R}^2 and orthogonal plane D_D is same in discrete case $E_D(x(t), v)$ (eq. 6.26).

$$\bar{E}_D(x(t), v) = \left\{ b \in \mathbb{R}^3 : b \in D_D(x(t), v), p = (b - x(t)) \to \mathbb{R}^2, \\ \left(\frac{p(1)^2}{d_{\theta}(x(t))^2} + \frac{p(2)^2}{d_{\varphi}(x(t))^2} \right) \le 1 \right\}, t \in \mathbb{R}$$
 (6.26)

The numeric calculation disproportion can occur in case that ellipsoid $\bar{E}_D(x(t), v)$ (6.26) in case of $d_{\theta}(x(t)) \approx 0$ and $d_{\varphi}(x(t)) \approx 0$. The count of ellipsoid members can be $|\bar{E}_D(x(t), v)| = 0$, which is in contradiction with assumption $|\bar{E}_D(x(t), v)| \neq 0$.

Let assume for discrete times $\tau = \{t_1, t_2, \dots, t_i\}$, $i \in \mathbb{N}^+$ there exists ellipsoids $\bar{E}_D(x(t_1), v), \bar{E}_D(x(t_1), v), \dots, \bar{E}_D(x(t_i), v)$ which are non empty and in space \mathcal{R}^2 in internal coordinate frame and space \mathcal{R}^3 in avoidance grid $\mathcal{A}(t_i)$ coordinate frame. The intersection of these partial ellipsoids in both spaces is equal to:

$$\bar{E}_D(x(t_1), v) \cap \bar{E}_D(x(t_2), v) \cdots \cap \dots \bar{E}_D(x(t_i), v) = \emptyset$$
(6.27)

An empty intersection enables us to keep homogeneity property of ellipsoids by adding points so it is safe to add specific point x(t) into empty ellipsoid. But only one, because it does not impact probability density functions $\mathcal{N}(\mu_{\theta}, \sigma_{\theta})$ and $\mathcal{N}(\mu_{\varphi}, \sigma_{\varphi})$, neither space intersection rate density function $P(x, d_{\theta}, d_{\varphi})$.

The final ellipsoid used forward $E_D(x(t), v)$ (eq. 6.28) is keeping all properties of ellipsoid E(x(t), v) (eq. 6.28).

$$E_D(x(t), v) = \begin{cases} |\bar{E}_D(x(t), v)| = 0 & : \{x(t)\} \\ |\bar{E}_D(x(t), v)| \ge 0 & : \bar{E}_D(x(t), v) \end{cases}$$
(6.28)

The normal distribution condition for rate distribution function $P_D(x(t), d_{\theta}, d_{\varphi}, p)$, which is instance of to rate density function $P(x(y), d_{\theta}, d_{\varphi})$ (eq. 6.20) is used. This rate distribution must be normalized according to (eq. 6.29).

$$\sum_{p \in E_D(x(t))} P_D(x(t), d_\theta, d_\varphi, p) = 1, \forall t \in \mathcal{R}^+$$
(6.29)

The equations for space intersection rate are similar to (eq. 6.22, 6.23). For cell $c_{i,j,k}$ there exist intruder entry time $i_e(c_{i,j,k})$ its the earliest intersection with ellipsoid $E_D(x(i_e(c_{i,j,k}))), v$. Same situation occurs with intruder leave time $i_l(c_i, j, k)$. Because E_D is countable set, it means additional attributes can be attached to each point $p \in E_D$.

Based on system dynamic (eq. 6.1) the *Time Of Arrival* (TOA) can be calculated. The example of TOA is given in fig. 6.5.

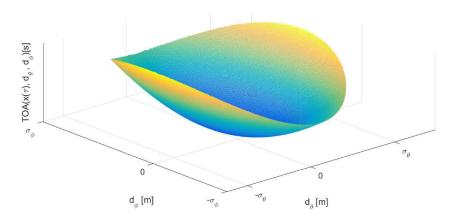

Figure 6.5: Time Of Arrival (TOA) for one ellipsoid $E_D(x(\tau), v)$.

The intersection rate $P_D(x(\tau), c_{i,j,k}, \theta, \varphi)$ for one time sample τ is given by (eq. 6.30), which has similar notation to (eq. 6.22), sums are used instead of integrals and discrete rate density function $P_D(x(\tau), d_{\theta}, d_{\varphi}, p)$ for points form ellipse and cell intersection are used as iterator base set $p \in \{E_D(x(\tau), v) \cap c_{i,j,k}\}$.

$$P_D(x(\tau), c_{i,j,k}, \theta, \varphi) = \sum_{p \in \left\{ E_D(x(\tau), v) \cap c_{i,j,k} \right\}} P_D(x(\tau), d_{\theta}, d_{\varphi}, p)$$
(6.30)

The space intersection rate $P_{TD}(i_k(x_s, v, \theta, \varphi), c_{i,j,k})$ (eq. 6.31) is given as mean intersection rate of partial intersections $P_D(x(\tau), c_{i,j,k}, \theta, \varphi)$ where step set $T = \{i_e(c_{i,j,k}), \ldots, i_l(c_{i,j,k})\}$ contains all viable intersection times with ellipsoids $E(x(\tau \in T), v)$. The denominator is basically count of samples in sample time set T.

$$P_{TD}(i_k(x_s, v, \theta, \varphi), c_{i,j,k}) = \frac{\sum_{\tau = i_e(c_{i,j,k})}^{i_l(c_{i,j,k})} \sum_{p \in E_D(x(\tau), v)} P_D(x(\tau), c_{i,j,k}, \theta, \varphi, p)}{\sum_{\tau = i_l(c_{i,j,k})}^{i_e(c_{i,j,k})} 1}$$
(6.31)

An intersection of intruder cone and cell $c_{i,j,k}$ cell is defined by (eq. 6.32) The set of point $p \in \mathbb{R}^3$ where condition of intersection between ellipsoids $E_D(x(\tau), v)$ for times $\tau \in \mathbb{R}^+$ and cell space $c_{i,j,k}$ is met.

$$\mathcal{P}(i_k(x_s, v, \theta, \varphi), c_{i,j,k}) = \bigcup_{\forall \tau \in \mathbb{R}^+} \left\{ p \in \mathbb{R}^3 : p \in c_{i,j,k} \cap E_D(x(\tau), v) \right\}$$
(6.32)

An intruder time of entry $i_e(i_k, c_{i,j,k})$ (eq. 6.33), for intruder i, k and cell $c_{i,j,k}$ is approximated for discrete point set $\mathcal{P}(i_k(x_s, v, \theta, \varphi), c_{i,j,k})$ (eq. 6.32) as minimal time of arrival $t_{TOA}(p)$ of member points p.

$$i_e(i_k, c_{i,i,k}) \approx \min \left\{ t_{TOA}(p) : p \in \mathcal{P}(i_k(x_s, v, \theta, \varphi), c_{i,i,k}) \right\}$$

$$(6.33)$$

An intruder time of leave $i_l(i_k, c_{i,j,k})$ (eq. 6.34), for intruder i, k and cell $c_{i,j,k}$ is approximated for discrete point set $\mathcal{P}(i_k(x_s, v, \theta, \varphi), c_{i,j,k})$ (eq. 6.32) as maximal time of arrival $t_{TOA}(p)$ of member points p.

$$i_l(i_k, c_{i,j,k}) \approx \max\left\{t_{TOA}(p) : p \in \mathcal{P}(i_k(x_s, v, \theta, \varphi), c_{i,j,k})\right\}$$
(6.34)

Combined intersection model: The combined intersection model $P_{O_I}(i_k, c_{i,j,k}, l, b, s, \tau)$ is defined for intruder i_k with parameters:

- 1. Starting position x_s expected position of intruder i_r in 3D space at time of avoidance t_i in avoidance grid frame $\mathcal{A}(t_i)$.
- 2. Velocity vector v oriented velocity of intruder i_r at time of avoidance t_i in avoidance grid frame $\mathcal{A}(t_i)$.
- 3. Horizontal uncertainty spread θ defines how much can intruder i_r deviate on horizontal axis of intruder local coordinate frame (if X+ is main axis, then Y is horizontal axis in right-hand euclidean coordinate frame), due the properties of intersection definition, the horizontal uncertainty spread can have following values $\theta \in [0, \pi/2]$.
- 4. Vertical uncertainty spread φ -defines how much can intruder i_r deviate on vertical axis of intruder local coordinate frame (if X+ is main axis in local right-hand euclidean intruder coordinate frame, then Z is horizontal vertical axis), due the intersection definition, the vertical uncertainty spread can have following values $\varphi \in [0, \pi/2]$.
- 5. Body volume radius r defines the body volume of intruder in meters and it is having \mathbb{R}^+ value.

The flag vector $l, b, s, \tau \in \{0, 1\}$ is parametrization of rate calculation: l stands for lined intersection, b stands for body intersection, b stands for spread intersection, b stands for time account.

The space intersection for line $P_L(i_k, c_{i,j,k})$ is defined as $P_T(i_k(x, v), c_{i,j,k})$, where i_k is intruder with properties of initial position x, velocity vector v and $c_{i,j,k}$ is target cell. (eq. 6.9).

The space intersection rate for body volume $P_B(i_k, c_{i,j,k})$ is defined as $P_T(i_k(x, v, r), c_{i,j,k})$ (eq. 6.13), where intruder i_r has additional property of the intruder body volume radius r.

The space intersection probability for maneuverability uncertainty $P_S(i_k, c_{i,j,k})$ is defined as $P_{TD}(i_k(x_s, v, \theta, \varphi), c_{i,j,k})$ (eq. 6.31), where intruder properties θ , φ stands for intruder horizontal and vertical uncertainty spread.

The time intersection rate $P_{\tau,x}(i_k, c_{i,j,k}) \in [0, 1]$ is defined in (eq. 6.5). This probability has two calculation modes, first is for 1D intersection (line), second is for volume intersection (body volume, spread elliptic cone).

UAS cell entry time t_e and cell leave time t_l time for vehicle in avoidance grid $\mathcal{A}(t_i)$ are given by (eq. 6.2) and (eq. 6.3).

Intruder leave and entry time for 1D intersections is trivial and is omitted in this section. Intruder entry i_e and intruder leave i_l for 3D intersection are given by (eq. 6.33, 6.34).

All partial rates with respective definition references are summarized in (eq. 6.35)

$$P_{L}(i_{k}, c_{i,j,k}) = P_{T}(i_{k}(x, v), c_{i,j,k})$$

$$P_{B}(i_{k}, c_{i,j,k}) = P_{T}(i_{k}(x, v, r), c_{i,j,k})$$

$$P_{S}(i_{k}, c_{i,j,k}) = P_{TD}(i_{k}(x_{s}, v, \theta, \varphi), c_{i,j,k})$$

$$P_{\tau,x}(i_{k}, c_{i,j,k}) = \frac{\|[i_{e}(c_{i,j,k}), i_{l}(c_{i,j,k})] \cap [t_{e}, t_{l}]\|}{\|[t_{e}, t_{l}]\|}$$

$$(6.35)$$

With definition of all space and time intersection rates (eq. 6.35) and given flag vector $l, b, s, \tau \in \{0, 1\}$ one can formulate combined intersection rate $P_{O_I}(i_k, c_{i,j,k}, l, b, s, \tau)$ (eq. 6.36) for intruder i_k and cell $c_{i,j,k}$. The principle is following: maximum of selected rates product based on flag vector is final intersection rate of intruder i_k in cell.

The time-use flag τ is adding time intersection rate $P_{\tau,x}(i_k, c_{i,j,k})$, where time intersection rate is defined by $x = \{L, B, S\}$ for line, body volume, spread ellipse time intersections $(P_{\tau,L}(i_k, c_{i,j,k}) \neq P_{\tau,B}(i_k, c_{i,j,k}) \neq P_{\tau,B}(i_k, c_{i,j,k})$ for one intruder i_k).

$$P_{O_{I}}(i_{k}, c_{i,j,k}, l, b, s, \tau) = \begin{cases} \tau = 0 & : \max \begin{cases} P_{L}(i_{k}, c_{i,j,k}).l \\ P_{B}(i_{k}, c_{i,j,k}).b \\ P_{S}(i_{k}, c_{i,j,k}).s \end{cases} \\ \tau = 1 & : \max \begin{cases} P_{\tau,L}(i_{k}, c_{i,j,k}).P_{L}(i_{k}, c_{i,j,k}).l \\ P_{\tau,B}(i_{k}, c_{i,j,k}).P_{B}(i_{k}, c_{i,j,k}).b \\ P_{\tau,S}(i_{k}, c_{i,j,k}).P_{S}(i_{k}, c_{i,j,k}).s \end{cases}$$

$$(6.36)$$

6.6.5 Moving Constraints

Idea: The basic ideas is the same as in case *static constraints* (sec. ??). There is horizontal constraint and altitude constraint outlining the constrained space. The only additional concept is moving of *constraint* on horizontal plane in global coordinate system.

The constraint intersection with avoidance grid is done in fixed decision Time, for cell in fixed cell leave time (eq. 6.3), which means concept from static obstacles can be fully reused.

Definition: The moving constraint definition (eq. 6.37) covers minimal data scope for moving constraint, assuming linear constraint movement.

The original definition (eq. ??) is enhanced with additional parameters to support constraint moving:

- 1. Velocity velocity vector on 2D horizontal plane.
- 2. Detection time the time when constraint was created/detected, this is the time when center and boundary points position were valid.

```
constraint = \{position, boundary, \dots \}

\dots, velocity, detectionTime, \dots

\dots altitude_{start}, altitude_{end}, safetyMargin\}  (6.37)
```

Cell Intersection: The intersection algorithm follows (eq. ??), only shift of the center and boundary points is required.

First let us introduce $\Delta time$ (eq. 6.38), which represents difference between the constraint detection time and expected cell leave time (eq. 6.3).

$$\Delta time = UAS_{leave}(cell_{i,i,k}) - detectionTime \tag{6.38}$$

The constraint boundary is shifted to:

```
shiftedBoundary(constraint) = \{newPoint = point + velocity \times \Delta time : \dots \\ \dots \forall point \in constraint.boundary\}  (6.39)
```

The constraint center is shifted to:

$$shiftedCenter(constraint) = constraint.center + velocity$$
 (6.40)

Note. The $\Delta time$ is calculated separately for each $cell_{i,j,k}$, because UAS is also moving and reaching cells in different times. The *cell leave time* can be calculated in advance after reach set approximation.

Alternative Intersection Implementation: The alternative used for intersection selected based on polygon intersection algorithms review [4], the selected algorithm is *Shamos-Hoey* [5].

The implementation was tested on *Storm scenario* (sec. ??) and it yelds same results.
